"Biochemical Processes in the Brain in Direct Irradiation by X-rays,"
N. N. Blokhin, B. M. Grayevskaya, and R. Ya. Keylina (Cent. Roentgenol.
Radiol. Cancer Inst., Leningrad.) Byull. Eksptl. Biol. Med., 23, 333-42 (1947)

X-ray irradiation of dog brain, at 160 kv., at 23 mm. distance by using
0.5 Cu-3.0 Al filter, each dog receiving a total of 5 unit skin doses of
irradiation in 4 exposures with alternate irradiation of the right and the left
temple area, was investigated in respect to biodhem. effects by detn.
of blood sugar (femoral artery and sinus venosus cerebri), spinal fluid sugar,
blood serum protein, and the albumin-globulin fractions of the latter. As the
total irradiation increased, the total serum portein rose until on the 90th
day (after the 1st irradiation) it rer hed 200% of the initial value. In the
same period the albumin fractions rose by only 26 % of arterial and 32% of venous
blood, while the globulin fraction rose 324 and 323%, resp. The abs. amt. of
protein in the spinal fluid remained within exptl. variations, but its albumin/
globulin ration gradually changed to 1.0 from 0.56 . Arterial blood sugar
remained normal, but it fell in the venous blood, until the sugar utilization by t
the brain at the 90-day period was 370% of initial.

"Effects of Aneurin (Vitamin B_1) on the Glycogen Formation Function of Liver of Rats During General Exposure to Various Doses of X-Rays," B. M. Grayevskaya, R. Ya. Keylina, and S. E. Manoylov, Dept of Biochem, Central Roentgenologic and Cancer Inst, Min of Health USSR

Vest Rentgen i Radiol, No 6, pp 22-25

Expts conducted on 15 rats showed that the glycogen formation function of the liver may be partially restored if vitamin B_1 is given after rats have

275T31

been exposed to X-rays. Enough evidence was collected to justify the assumption that the quality of biochem changes in the organism of rats depends upon the extent of exposure to X-rays: small doses (500 r) of X-rays suppress the oxidation systems of the whole organism: larger doses (1,000 and 2,000 r) also cause breakdown of the substances that oxidize. It is possible that interference with the synthesis of the dehydrogenase coenzyme takes place and that vitamin B_1 loses its capacity to combine with phosphoric acid. This follows from a reduction of the restorative effect of vitamin B_1 on the liver.

KEYLINA, R. Ya.

Alterations in carbohydrate metabolism after irradiation of total animal organism. H. M.
R. Ya. Keilina. *Trudy Konferentsii i Radiol.* 1955.
21-6 —Total-animal (dogs) irradiation caused disturbed liver function and disturbed responses to adrenalin and glucose. At sublethal (300-500 r.) and lethal doses the glycemic curves after treatment with adrenalin and glucose are different: in the 1st instance they show slopes with a hyperglycemic and 1 1-1.2, while in the 2nd instance they have the diabetic character (coeff. about 1). After such irradiation there is at first a considerable disorder of sugar utilization by the brain, while in later stages there occurs an actual elimination of sugar by the brain as shown by the outflowing blood, which is never observed in normal animals. At the low-dose level the animals combat the injury and are restored in some 4 days; at high levels of irradiation the process is irreversible and the glycogen-forming function of the liver is impaired for life. —G. M. Bogdanoff.

KEYLINA, R. YA.

"Changes of the Sugar Content of Blood Leaving the Brain and Muscles After Total Irradiation of Dogs by X Rays," by R. Ya. Keylina, Vopr. Radiobiologii (Problems of Radiobiology), Leningrad, 1956, pp 347 - 351 (from Referativnyy Zhurnal -- Khimiya, Biologicheskaya Khimiya, No 1, 10 Jan 57, Abstract No 702

After irradiation of dogs by X rays (300 - 500 r), the sugar consumption of the brain sharply decreased, reaching zero toward the 40th day, but starting with the 50th day there was an insignificant release of sugar into the circulating blood. However, the muscles at this time started to use up sugar intensely.

Following total irradiation of dogs by lethal doses (1,000 r), a high sugar content was maintained for 4 hours in the arterial blood subsequent to adrenalin injections.

Shifts detected in the carbohydrate metabolism following X-ray irradiation are evidences of disturbances of a number of enzyme systems participating in the breakdown and oxidation of glucose.

Sum. 13 05

"Change of Carbohydrate Metabolism Due to Total Irradiation
of an Animal Organism by X Rays," by B. M. Grayevskaya and
R. Ya. Keymina, Voprosy Radiobiologii (Problems of Radio-
biology), Leningrad, 1956, pp 352-356 (from Referativnyy
Zhurnal -- Khimiya, Biologicheskaya Khimiya, No 24, 25 Dec
56, p 80, Abstract No 23449)

Subcutaneous injections of adrenalin to dogs who were subjected to
total irradiations by 300 to 500 r did not cause increased blood glucose
content. Liver glycogen content decreased 80% in 48 hours after irradi-
ation.

Glucose administration caused no glycogen synthesis in the liver of
rats who had been subjected to 500, 1,000, or 2,000 r.

Kellis-Borok, V. I. On the frequency equation of a multi-layered elastic medium. Doklady Akad. Nauk SSSR (N.S.) 87, 25-28 (1952). (Russian)

L'auteur considère un espace élastique composé de n couches planes, parallèles, homogènes, et isotrope+un demi-espace homogène et isotrope, les épaisseurs et autres caractéristiques de couches étant quelconques. Ce système est soumis à des tensions produisant des déformations, les unes et les autres étant fonctions continues des coordonnées. Sur la frontière du système les tensions normales sont nulles. En représentant les solutions des équations des ondes par les intégrales Fourier-Bessel dans le cas de symétrie axiale l'auteur forme l'équation caractéristique dont les solutions donnent les fréquencies des ondes. Il montre que les ondes libres sont possibles et que, à une distance suffisamment grande de la source, on peut avoir des ondes forcées d'un type spécial; leur vitesse de phase et l'intensité dépendent de la fréquence et de l'épaisseur des couches. La note donne les formules assez compliquées sans définitions et sans démonstrations.   V. A. Kostitzin (Paris).

KEYLIS-BOROK, V. I.

AUTHOR: Keylis-Borok, V. I.   49-4-3/23

TITLE: On the theory of waves generated during shear.
           (O teorii voln, voznikayushchikh pri sdvige).

PERIODICAL: Izvestiya Akademii Nauk, Seriya Geofizicheskaya,
             1957, No.4, pp. 440-448 (USSR)

ABSTRACT: The relation is investigated between a point source of
           elastic waves (a model simulating the focus of an
           earthquake) and the static displacements which occur
           after passage of these waves. An analysis is made of
           the static field, described by means of the dislocation
           theory as formulated by Love for shear dislocations,
           and the possibility of application of this theory to
           simulating such focussion models.   In the case of
           correct analysis, the conclusions derived from the
           dislocation theory are in agreement with generally
           accepted conceptions relating to a shear wave in
           the shape of a dipole with a moment. Vvedenskaya, A.V.
           (Ref.4) attempted to find a shear model by means of the
           Love dislocation theory, considering as a model of the
           elementary shear two perpendicular dipoles with a
           moment as indicated in Fig.2 and not one dipole with a
Card 1/5   moment. The dependence of the intensity of the source

           on the time is thereby so chosen that the main part of the
           dislocations is represented by the Dirac δ-function,
           referred to in this paper as the Nabarro source; the
           displacements described by the Nabarro formula (Ref.5) are
           integrated along a circle which simulates the sliding
           plane in the tremor and it is assumed that the obtained
           expressions describe waves which occur during shear,
           taking into consideration the presence of fault.
           It is shown in this paper that Nabarro did not generalise
           the theory of dislocations for the dynamic case and
           introduced certain assumptions without any proof; extension
           by Vvedenskaya of the respective interpretation led to
           erroneous results, even if it is assumed that the assumptions
           of Nabarro are correct. Application of the theory of
           dislocations in modelling of earthquakes is fundamentally
           based on the assumption that residual deformations are
           absent in the focus; even for this assumption, the results
           obtained from the theory of dislocations are practically
           equal with those obtained in earlier work of the author
           (Refs.1 and 2).   The theory of dislocations in the sense
           expressed by Love describes the state of a continuous
Card 2/5   medium and permits determination of a source with static
           forces with equivalent dislocations, i.e. sources which

TITLE: An Investigation of the Earthquake Mechanisms

PERIODICAL: Byull. Soveta po seysmologii AS USSR, 1957, Vol 16, pp 96-99

ABSTRACT: This is a brief survey of the work of Soviet authors on the
            mechanisms of earthquakes. The analysis of the investigation
            results of about 300 earthquakes in the main seismoactive zones
            of the USSR and adjacent regions leads to the following pre-
            liminary conclusions: 1) The predominant properties of dis-
            locations in the earthquake source vary sharply with the transition
            from one tectonic section to another one. There is also no direct
            link of dislocations in individual sources with local tectonic
            surface fractures. 2) In regard to the strike of the basic
            structures, the predominant strike of dislocation is transverse
            for the NW part of the Pacific Ocean, Dagestan, the Akhalkalaks-
            koye highlands, and longitudinal for the Ashkhabadskiy rayon.
Card 1/2   But in the majority of zones (Garmskaya oblast', Tien Shan,

An Investigation of the Earthquake Mechanisms   SOV/169-59-3-2207

Shemakha), two predominat strikes are distinguished, the longitudinal and the transverse strikes. A gradual change of the strike of dislocations in the foci from transverse to longitudinal is to be noticed in the Prikazbekskiy rayon of the Caucasus with increasing distance from the zones of transverse fractures. 3) The horizontal components of the displacements in the foci have great intensity. 4) The vertical components of the motion in the foci of some districts (West-Turkmenistan, Caucasus, Tien Shan) have a peculiarity consisting in a lift of the reverse wing, located on the side of the depression. In general, the results adduced coincide with the neotectonic data for a number of regions, where recently formed surface dislocations differ from the basic, older structures, approximately in the same manner as the dislocations in the earthquake foci described by the authors.

Khaykovich, I.M. Beam Method of Computing the Wave Intensity in
a Relaxing Medium With a Large Relaxation Time   179
   The author refers to various scientists offering the solu-
   tion of nonstationary problems in the theory of elasticity
   leading to the determination of the intensity and the force
   of reflected waves. He introduces a so-called beam method
   for computing the propagation of a wave in nonideal elastic
   media. The following names are mentioned: G.I. Petrashen',
   V.M. Babich, G.O. Gurevich.

Sherman, D.I. Problem of the Stressed Condition of a Semiplane
Without External Load and With Two Sunken Circular Orifices   187
   The article discusses the distribution of stresses caused
   by gravity in media weakened by holes or openings. The
   problem is of interest in analyzing the rock pressure in the
   neighborhood of shaft openings and for the study of seismic
   conditions.

TITLE: Dispersion of the Rayleigh Waves in a Two-Layer Model
            of the Earth's Crust (Dispersiya releyevskikh voln
            v dvukhsloynoy modeli Zemnoy kory)

PERIODICAL: Izvestiya Akademii Nauk SSSR, Seriya Geofizicheskaya,
            1959, Nr 1, pp 27-31 (USSR)

ABSTRACT: In order to improve the data for the Earth's crust
            calculated by the dispersion method, a two-layer
            dispersion method is proposed. The calculation is based
            on the half-space $z > 0$ covered by two layers:
            $0 > z > -m_1$ and $-m_1 > z > -(m_1 + m_2)$.
            The base and the two layers are composed of a
            homogeneous medium which is also isotropic and ideally
            elastic. The phase velocity v of the Rayleigh waves
            in such a medium can be represented by Eq.(1), where
            m_q - thickness of q-layer,
            a_q, b_q - velocities of longitudinal and transverse
                    waves respectively,
Card 1/4 u_q - a constant (q = 1, 2, 3 denote top, middle layers
                    and base respectively).

Dispersion of the Rayleigh Waves in a Two-Layer Model of the Earth's Crust

The relationship of these values is calculated from the following:

$$\sigma_q = \mu_{q+1}/\mu_q; \quad \alpha_q = \sqrt{1 - v^2/a_q^2}; \quad \beta_q = \sqrt{1 - v^2/b_q^2}; \quad \gamma = 2 - v^2/b_q^2;$$

$$s = 2(\sigma_1 - 1) + v^2/b_1^2, \quad c = 2(\sigma_1 - 1) - \sigma_1 v^2/b_1^2; \quad d = c + v^2/b_1^2;$$

$$X_{i_\alpha} = \text{ch } \alpha_i \xi m_i; \quad Y_{i_\alpha} = \text{sh } \alpha_i \xi m_i; \quad X_{i_\beta} = \text{ch } \beta_i \xi m_i; \quad Y_{i_\beta} = \text{ch } \beta_i \xi m_i.$$

(ξ – wave characteristic, $\xi = p/v$, p – rotational frequency). The dispersion surface is equal to $v/b_3 = f(\lambda/m_1, \lambda/m_2)$, where $\lambda = 2\pi(b_3/p)$ – the length of the transverse wave with frequency p. It is divided into successive parts according to the different harmonics (Refs 2,4,5). For computation on hand machines it is better to find the solution of ξm_1 with given

Card 2/4

Dispersion of the Raleigh Waves in a Two-Layer Model of the Earth's Crust

v/b_3 and m_2. The results obtained by means of the electronic machine BESM, Ac.Sc., USSR are shown in Figs. 1-4. The constants used were those for the Central Asia (Refs 6,7) $a_3/b_3 = 1.85$, $a_2/b_3 = 1.46$; $a_1/b_3 = 1.28$, $b_2/b_3 = 0.88$, $b_1/b_3 = 0.76$, $\sigma_1 = 1.48$, $\sigma_2 = 1.48$ (a_3, b_3 - the outer surface). Fig.1 shows the data of the dispersion surface: the curves of the phase v and the group velocity V of the first harmonic for various values of $\varphi = $ arc tg m_1/m_2.

The limiting values of v/b_3 (as related to the Raleigh waves) are 0.9265 for $\lambda \rightarrow \infty$, 0.6923 for $\lambda = 0$, $\varphi \neq 0$, 0.8011 for $\lambda = 0$, $\varphi = 0$. Figs.2-4 show the surface v/b_3 (for second, third and fourth harmonics). When $V/b_3 \approx 0.7$ for $\lambda = 0$ and m_1/m_2 is small, the group velocity has a second minimum in high frequencies (Ref 1). It can be seen from Fig.1 that when the value

Card 3/4

Dispersion of the Rayleigh Waves in a Two-Layer Model of the
Earth's Crust

of m_1/m_2 increases, the equivalent value $(m_1 + m_2)$
decreases. This is explained by a decrease of the
wavelength due to $b_1 < b_2$. In order to determine
m_1 and m_2 by means of the curves (Fig.1), it is
necessary to find the dispersion V in the homogeneous
region so that the respective value of b_3 can be
established. (The notations of Fig.1 are as follows:
1 – phase and 2 – group velocities, 3-6 – experimental
data for Rayleigh waves in various localities (Ref 1)).

TITLE: Magneto-elastic Waves and the Boundary of Earth Core

PERIODICAL: Izvestiya Akademii nauk SSSR, Seriya geofizicheskaya,
            1959, Nr 11, pp 1529-1541 (USSR)

ABSTRACT: The authors describe results of their investigations of
            the dispersion, damping, polarization and origin of
            magneto-elastic waves. The damping of waves with an
            increase of the field strength H_0 attains a certain
            maximum value from which it gradually tends to 0. Two
            types of waves can occur in a strong field: slow waves
            with a velocity between the transverse and longitudinal
            elastic waves, and fast waves with a velocity
            proportional to H_0. An intense mechanical vibration
            can only be caused by slow waves. The characteristics
            of the latter, being similar to longitudinal or
            transverse waves, depend on the direction of their
            propagation and are not affected by the initial pulse. The
            observed range of velocities of seismic waves in a
            stratum D" can be explained by a linear increase of
            the gradient k/ρ and by a decrease of u/ρ (see table)
            due to compensation by the magnetic field. The
            existence of transverse waves in the core can be

Card 1/2   explained by a presence of the magnetic field μ

SOV/49-59-11-1/28

Magneto-elastic Waves and the Boundary of Earth Core

            unless there is a layer 20 to 80 km thick at its surface
            with an increased resistance (to $\sim 0.4 \times 10^{-8}$ sec) or
            there is a radial   field with a strength $\sim 10^9$ to 10^{10}
            oersted. An increase of the phase velocity v of
            longitudinal and transverse (dashed lines) waves is
            illustrated in Fig 1, where the numbers on curves
            denote a squared strength of the field ϕ. Fig 2 shows
            the polarization of vibration in a weak field. Fig 3
            illustrates the phase velocity of vibrations in a
            strong field. Fig 4 gives the coefficients of damping
            with distance in a weak field where the magnitudes of
            $e^{-K_\perp x\omega/a}$, $e^{-K_\parallel x\omega/a}$ determine   damping with a distance
            x of longitudinal and transverse waves respectively.
            Thanks are conveyed to G. S. Golitsyn, V. A. Kalinin and
            R. Khayd for their assistance. There are 4 figures, 1
            table and 12 references, 6 of which are Soviet and 6

   T.V. Polyakova.

PURPOSE: This book is intended for geophysicists, seismologists, meteorologists,
   and oceanographers.

COVERAGE: This is a study of oscillations of a layered elastic medium (plane-
   parallel, uniform, isotropic, and ideally elastic layers) from a single viewpoint.
   The general physical and mathematical description of the oscillations is suitable
   for direct analysis of the mathematical derivation and for studying the solutions
   together with the system of boundary conditions, without resorting to cumbersome
   solutions of elastic theory problems. This approach made it possible to obtain
   general results for any number of layers and for practically any nonsymmetric,

TITLE: Studies of the dislocations at earthquake foci

PERIODICAL: Referativnyy zhurnal. Geofizika, no. 11, 1961, 14-15,
            abstract 11A141 (V sb. Probl. tektonofiziki, M., Gos.
            geoltekhizdat, 1960, 309)

TEXT: A method permitting determination of the properties of dis-
locations at an earthquake focus from seismic data (the mechanical
type of fracture, the dip and strike of the plane of fracture, the
direction of movement) was elaborated. About 300 earthquakes were
investigated in the main seismically-active zones of the Soviet
Union and adjoining regions: the north-west edge of the Pacific
Ocean, the Hindukush, the Pamirs and Tyan'-Shan', Kopet-Dag and
Western Turkmeniya, and the Caucasus. On the whole, the disloca-
tions at the foci have approximately the same similarities to and
differences from the main tectonic structures as those which have
been formed in recent times and which are distinguishable in neo-

Card 1/2

Studies of the dislocations at ...   S/169/61/000/011/006/065
                                            D228/D304

tectonics. Dislocations with a transverse strike and with intense
horizontal components of movement are evidently noted more frequent-
ly at the foci than is the case in surface structures. Vertical mo-
vements at the foci of a number of areas are characterized by the
uplift of the limb of the fracture which has been turned to the si-
de of the tectonic depression. This agrees with the data of neotec-
tonics and with some results of abyssal seismic sounding. [Abstrac-
tor's note: Complete translation].

TITLE: Methods of the detailed study of seismicity

PERIODICAL: Referativnyy zhurnal, Geofizika, no. 10, 1961, 12-13,
                 abstract 10A144 (Tr. In-ta fiz. Zemli AN SSSR, no. 9,
                 1960, 327 p.)

TEXT: The Tadzhik complex seismologic expedition was organized with
the aim of studying the nature of earthquakes and the conditions of their
genesis. The most seismically-active zones of the USSR (Garmo and Stalina-
bad) were chosen as the work areas. The specific conditions of working
and processing the data demanded the development of special systems of ob-
servation and methods of interpretation. The large amount of recorded

Card 1/6

Methods of the detailed...

S/169/61/000/ 010/009/053
D228/D304

seismic phenomena permitted the use of statistical methods for studying
their distribution in space and time; these methods, in their turn, pro-
vided the basis for introducing the quantitative indices of the seismicity
characteristics of the seismically-active areas. The actual seismic ob-
servations were closely coordinated with geologic investigations, and this
provided the possibility of exposing the tectonic basis of the seismic
phenomena. A general review of the work area is given in Chapter 1, and
concise data on major earthquakes are cited together with the general posi-
tion of the expedition stations. A description of the standard main and
auxiliary apparatus used at the stations, and also the layout and descrip-
tion of newly developed equipment--including an automatic seismic station
with a magnetic memory--is cited in Chapter 2. The methods developed and
utilized in the expedition for studying the crust's structure in the area
under investigation from the records of nearby earthquakes are described
in Chapter 3. Horizontal and vertical hodographs were constructed. The
resulting material enabled the crust to be represented as a one-layer mass

Card 2/6

Methods of the detailed...

S/169/61/000/010/009/053
D228/D304

with a longitudinal-wave velocity of 6.0 – 6.1 km/sec. At the Mohorovicic boundary, the velocity suddenly changes to 8.0 km/sec. and then somewhat decreases, but at a depth of 300 km it subsequently increases to 9.2 km/sec. These data underlay the construction of isochrone charts used to localize the epicenters and to determine the focal depths. The isochrone charts were constructed with an account of the heterogeneity of the work area's geologic structure and the peculiarity of the seismic stations' location. This enabled the precision of hypocenter localization to be substantially increased, reducing it to 1 – 2 km at the center of the work area's topographic map. In Chapter 4, the definition of the concept of seismic energy at the focus is given, and the basic formulas are derived for its calculation. On the basis of experimentally obtained laws for the dying out of energy with distance, nomographs were constructed to determine practically the energy at the focus from the records of nearby earthquakes. Appraisal of the precision of calculation of the energy in relation to different factors shows that it may be determined accurately to the order of its magnitude. In this connection, the value $K = lg\ E\ j$.

Card 3/6

Methods of the detailed...

S/169/61/000/010/009/053
D228/D304

is introduced for characterizing the energy class of earthquakes. The value of K is compared with the earthquake magnitude M. The study of the iso-energy lines shows that the different degrees of the dying out of seismic energy along and across the strike of geologic structures exert a decisive influence on the form of the isoseisms. In Chapter 5, the frequencies of seismic vibrations are studied--in relation to the earth-quake energy, the distance from the source, the geologic conditions at the point of observation and at the hypocenter, etc.--from recordings at both the customary stations and a special ЧИСС (ChISS) seismic-station intended for frequency analysis of seismic waves directly at their place of registration. A detailed description is given for the frequency-selective seismic-station ЧИСС-1954 (ChISS-1954) and for the results of the investigation of its recordings. Certain epicentral zones with an anomalous frequency are thereby revealed. The procedure for theoretically calculating the focal characteristics, and also for appraising these latter from empirical data, is given in Chapter 6. Several formulas are

Card 4/6

Methods of the detailed...

S/169/61/000/010/009/053
D228/D304

cited for determining the size of a focus in relation to its energy on the
basis of different physical propositions. The dynamic parameters of the
foci are determined; there appear to be definite predominant directions
for both the strike and dip of the fracture planes. The characteristics
of the seismic conditions of the Garmo and Stalinabad seismically-active
regions--both as a whole and in individual areas--are quoted together with
the variations in the parameters of the conditions in time. The quantita-
tive expression of the seismicity during constant seismic conditions is
determined by the seismic activity. The possibility is shown of construct-
ing graphs of the recurrence of earthquakes from short observations of
weak shocks, and methods are given for determining the period required to
obtain the parameters of he seismic conditions with a pre-set precision
in relation to the energy of the recorded earthquakes. The statistical
constancy of the seismic conditions is determined by the so-called measure
of dispersion of the frequency of earthquakes. A brief description of the
area's stratigraphy and the history of its geologic development is given
in Chapter 8. The structural schemes and descriptions of the most important

Card 5/6

Methods of the detailed...

S/169/61/000/010/009/053
D228/D304

deep faults are cited. The contemporary structure of the Garmo area is depicted as two main regions: the alpine geosynclinal zone in the south and the activated epi-Hercynian platform in the north. In section, it is drawn as several steps of Paleozoic basement adjoining each other along deep faults. A comparison of the seismicity with the tectonics of the study areas is made in Chapter 9. The construction of maps of isolines of seismic activity and gradients of the rate of tectonic movements is recommended for appraising the connection between the seismicity and the tectonics. Methods are cited for constructing such maps. The congruence between these magnitudes is established for the regions under investigation, and areas with the maximum gradient values correspond to those with the highest values of seismic activity. 272 references. /Abstracter's note: Complete translation./

AUTHOR: Keylis-Borok, V. I.

TITLE: The difference of the surface wave spectra of earthquakes and underground explosions

SOURCE: Akademiya nauk SSSR. Institut fiziki zemli. Trudy, no. 15 (182), Moscow, 1960. Seysmicheskiy effekt podzemnykh vzryvov, 68-101

TEXT: The dependence of the surface wave spectrum of the Rayleigh and Love type on the spatial properties of the source is investigated for the case of the most simple explosion and earthquake models. The effect of the dimensions and shape of the source on the surface wave spectrum and the intensity distribution in this source in the case of a given frequency spectrum of perturbance stresses is studied. Based on formula

$$U \approx R_A\left(\frac{p}{v},\phi\right) P_U\left(\frac{p}{v},z_0\right) Q(p) \frac{1}{\sqrt{r}} \; e^{-i\frac{p}{v}r} , \qquad (2)$$

where R_A is the spectrum of the source according to distance, and on other calculations in the article, the author compares the surface wave spectra

Card 1/3

The difference of the surface wave spectra ...

for the accepted earthquake and explosion models. Formula (2) shows that
the difference in the surface wave spectra will be defined by the functions
of R which are independent from the structure of the medium. The calcula-
tions show that the difference between the sources is mainly determined by
their dimensions. The greater the dimensions, the longer will be the pre-
dominant surface wave period. At the same time, the dimensions of the
earthquake focus are much larger than those of the explosion zone. Conse-
quently, the surface wave periods during earthquakes are also much longer
than during explosions. It was established that there is a great differ-
ence among the surface wave spectra, but no difference in the spectra of
volumetric waves. During earthquakes the stress concentration is consider-
ably smaller than in explosions of the same energy level. So, in explo-
sions, the non-elastic deformation zone will be much smaller. The depth of
the source of earthquakes is larger than that of explosions. The theore-
tical conclusions of the author agree with experimental data taken from the
paper of S. D. Kogan, I. P. Pasechnik, and D. D. Sultanov (Ref. 7: "Dokl.
AN SSSR", 29, No 6, 1959.). For an explosion of 1 kg of explosives (accord-
ing to a report by D. A. Kharin), the seismic wave energy was $4 \cdot 10^{17}$ erg
and the destruction zone diameter ranged between 150 and 200 m. It was

Voprosy teoreticheskoy seysmologii i fiziki zemnykh nedr, 117-124

TEXT: In earthquakes, both rarefaction and compression waves are radiated from the
focus, whereas in explosions only compression waves are generated. There is, however, a
small but finite probability (of the order of 1/5) that even in case of earthquakes only
compression waves are recorded at all observation points. In this case, earthquakes are
distinguished from explosions by the sign of the first arrivals of the transverse SV
waves as recorded on stations within a sufficiently wide range of azimuths: negative SV
arrivals are characteristic of earthquakes, whereas positive SV arrivals characterize an
explosion. There are 8 figures.

TOPIC TAGS: upper mantle, hodograph, seismic wave, Monte Carlo method

ABSTRACT: The problem of determining the structure of the Earth's upper mantle from the
hodographs $t(\Delta)$ of the first few arrivals lacks a unique solution. This ambiguity may be
markedly offset, however, if the amplitude curve $A(\Delta)$ or $A^*(\Delta) = \log A(\Delta)$ of direct re-
fracted P waves is also utilized. Travel-time curves which hardly differ in $t(\Delta)$ may be
characterized by different $A^*(\Delta)$ and analysis of the latter can result in a marked reduction
of the set of curves obtained. The following method of solution of the reciprocal problem is
proposed: the sought travel-time curve TTC is parametricized, i.e. represented by a specified

Card   1/2

UDC: 550.34-517:681.142.35

ACC NR: AT6033690

function of the parameters. The possible ranges of variation in these parameters, i.e. the region within which the true travel-time curve exists, are indicated, and individual TTC are scanned, on theoretically calculating for each TTC the data known from observations. The discrepancy between the computed and observational data then is calculated. The set of travel-time curves for which this discrepancy is sufficiently small represents the solution of the problem. Thus, the problem reduces to finding the region of the minimum of multivariate function (discrepancy between calculations and experiment) in the space of unknown parameters of TTC. Finally, the set thus identified must be compactly described, i.e. the common features of all the TTC thus found must be pointed out. The determination of the limits of the parameters and the selection of the type of the parameter-dependent function and the optimal method of search for the minimum depend on the conditions of solution of the converse problem in every particular case: on the accuracy of observational data, type of A (Δ), epicentral spacing for which t (Δ) and A (Δ) are specified, and the nature of the known and unknown parameters. Thus, e.g. if constraints are imposed on both velocities (according to t (Δ)) and velocity gradients (according to A (Δ)), of the methods used to search for the minimum the Monte Carlo method proves to be best. TITLE: The use of electronic computers in studying the structure of the earth's crust

SOURCE: AN SSSR. Izvestiya. Seriya geologicheskaya, no. 1, 1967, 3-10

TOPIC TAGS: earth crust, earthquake, electronic computer, computer programming, computer application

ABSTRACT: The author presents an attempt to formalize computer operations for seismic data in order to obtain information concerning the structure of the Earth's crust. The first task is to find parameters describing the data succinctly while avoiding the loss of essential information. Earthquakes represent an important characteristic of crustal deformation; they occur in great numbers, each reported by coordinates of the epicenter, origin in time, intensity, and so forth. Other parameters are unrelated to tectonics. Total number shocks and energy are more preferable parameters, but still not representative. The author has chosen the sum of energies of individual earthquakes, raised to the 2/3 power, because it is convenient, concise and approximately proportional to the sum of the fracture areas of rupture at the foci. Summation was carried out on

Card 1/2   UDC: 681.142.35:550

a sliding time scale, the sum at any moment being obtained by summing earthquakes for a certain number of years preceding that moment. This number of years varied for different studies, but was 3, 4, or 5 for examples illustrated in the paper. Consideration was given to areas involved in the summation (such as all the Himalayas for the Assam earthquake, the Pamirs, Hindukush, and Tien Shan for the Khait earthquake). Conclusions concerning the structure of the crust were in conflict because of the problem of selecting data, or the inability to handle all data. The solution of this problem lies in the recognition and elimination of ambiguity. In this study, records of several kinds of waves (longitudinal, transverse, Love, and Rayleigh) were used to investigate a section of the crust between Andizhan and Frunze. Results show a reliability range for seismic velocities down to depths of 60 km on the basis of two models: one with one intracrustal discontinuity (base of the sedimentary layer), the other with two such discontinuities (base of the sedimentary layer and the "granite-basalt" boundary). The outline of the computer program is broken down into four stages: 1) analysis of records at a single point, 2) study of earthquake foci, 3) refinement of basic empirical patterns, and 4) final conclusions, including sections of the earth, description of seismicity, and methods of recognizing faults. The author concludes that this method of treating seismic data should be more widely used. Orig. art. has: 6 figures. [04]
